

Brown Field Services and Interior Design

DRAFT

What color is your IP Address?

Allan Eising
Network Automation Architect

Goal

By the end of this presentation, you should:

- Understand the problem caused by automation in brown-field services
- Understand the process of reconciliation

Explaining reconciliation as interior decoration

Greenfield

- In a greenfield scenario your automation will start with an empty room
- The walls are white, and no furniture exists

Service

- Services are declarative
- They describe an end result
- It describes how the room should look:
 - Three chairs
 - One table
 - A sofa
 - The walls should be green

Furnishing

- To get the empty room to the intended state, a number of steps will be taken
- Here:
 1. Paint the walls green
 2. Add the furniture

Service Diff

- The service can be recorded as the difference between the two rooms
- This difference can be broken down into a set of steps
 1. Paint the walls
 2. Install three chairs
 3. Set up dining table
 4. Place the sofa

Create, modify, delete

- This diff allows us to have Atomic operations:
- If you record how to go from the empty room to the desired state, you can do the opposite too:
 1. Remove the furniture
 2. Paint the walls back to their original color
- If you modify your service, you just have to remove the old one, and re-apply your modifications

Brown-field

What happens if the
room isn't empty?

Brown field

- What if instead of an empty room, there is already something in it?
- The walls have a different color
- Some of the furniture is already there
- There's completely unknown furniture too, a book case!

Reaching the intended state

- Your orchestrator should apply the design on top of the original room
- The walls will be re-painted to green
- the missing two chairs will be added
- The sofa will be added
- But the bookcase will remain untouched

Removal

- Removing the service will restore the room to its original state
- Including the old paint and the furniture that was already there

Questions

- The color of the wall represents some configuration that your service includes that had a different value before
- Which color is the right one?
 - The one that was already in the network
 - Or the one that your service applies?
 - Can you name an example of this from the real world?
- The bookcase represents configuration that isn't part of the service
 - Should it actually be there?
 - Should it have been removed by your service?
 - Can you name an example of this from the real world?
 - What would you want your orchestrator to do in your example?

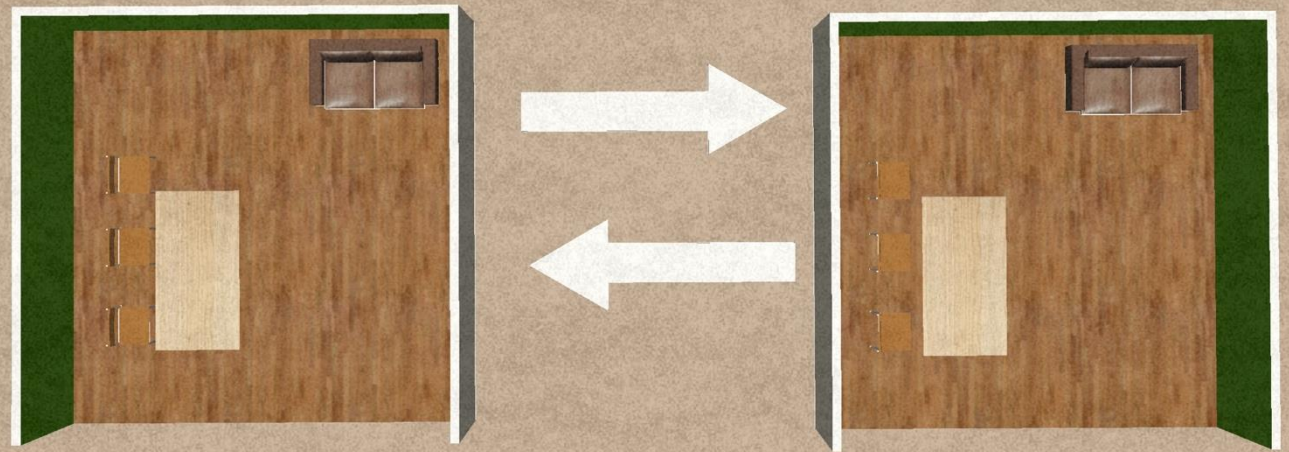

Examples

- Configuration that is different in the network
 - A different VLAN
 - An interface description with the customer name spelled differently
 - A higher or lower MTU value
- Configuration that is not part of the service
 - Something manually configured
 - Something that the router adds automatically

What if it was right from the start?

- When the automation is run, it has actions to run
- But once the service is deleted, there are no steps to reverse
- This means that the service is removed, but the result of the service is still in the network
- We thought we removed the service, but it is actually still there!

Reconciliation

How can we do the right thing?

Reconciliation

- With cisco NSO, it doesn't remove what it didn't create
- So we need to "trick" it in to believing that it created all of it
- This is done with the "reconciliation" process

What about the bookcase?

- You need to choose what to do with the elements that are not part of your service
- Keep or remove?
- There are pros and cons to both

Going a little deeper

Service meta data in NSO

Ref-counts

- NSO counts how many times an item is referenced by a service
- If a service adds an item that doesn't exist, it has count **1**
- If a service wants to add something that is already there, it adds **1** to the ref-count
- If a service is removed, and the counter reaches 0, the item is removed

Backpointers

- Each service also leaves its address on each item
- This allows us to tie the ref-count to the actual services

Service meta data

Ref-count: 2

backpointers

- Service 1
- Service 2

Brownfield

- If something already exists, it will get a ref-count but no backpointer
- The bookshelf is not part of the service, so it will have no ref-count
- Original values of items changed will also be recorded

Service meta data

Ref-count: 2

Original value

Blue

Service meta data

Ref-count: 2

backpointers

- Service 1

Well actually...

- It is possible to “hide” some of the changes from NSO, for example:
- We can create things that are not removed afterwards
- We can do a “no shutdown” on an interface without making NSO issue a “shutdown” on removal.

Reconciliation

Resolving differences – why is
this hard?

Who is right?

- Was the wall actually supposed to be blue?
- How many chairs did the customer actually want?
- Did the customer actually order a book case but we didn't support that in NSO or our standard product?
- This requires some insight in to the customer order

Who is right? (with proper examples)

- Was the ~~wall~~ **vlan** actually supposed to be ~~blue~~ **101**?
- How many ~~chairs~~ **megabit/s** did the customer actually want?
- Did the customer actually order a ~~book case~~ **OSPF** but we didn't support that in NSO or our standard product?

Challenge at scale

- Some of the original states might have been correct
- Some are obviously incorrect
- But it may be hard to tell without knowing
- There may be thousands of services to analyze

Summary

- Recording the difference in state is a very powerful way to run an orchestrator, as it allows:
 - Using a declarative model that works together with what is already in the network
 - Recording steps taken to create the service, and reversing it when deleting
- However
 - This can lead to partial or complete configurations being left when deleting services
 - Misconfiguration might hide in the state before the service was created
 - Configuration not handled by the service could be left behind
- You must decide what to do:
 - Unhandled config can be kept or removed.
 - Values that were different should be understood, as they will disappear after reconciliation
 - This can be a challenge at scale.
